Summation of Smooth

- Type of generalized linear model
- Response variable depends on smooth functions $f_i(x_i)$
- General structure of a GAM:
$$g(E(Y)) = \beta_0 + f_1(x_1) + f_2(x_2) + \cdots + f_n(x_n)$$
- Smooth functions can be many different things (polynomials, splines, weighted means, etc)

Generalized Additive Models

A Linear Model sums the linear terms

$$y_i = \beta_0 + \sum_j \beta_j x_{ji} + \epsilon_i$$

GAMs sums the *smooth functions*

$$y_i = \beta_0 + \sum_j s_j(x_{ji}) + \epsilon_i$$

Where

$$\epsilon_i \sim N(0, \sigma^2), y_i \sim \text{Normal}$$

Splines

A *Spline* is a function made of up basis functions (the smoothing functions)

These simpler functions form a set of functions called the *basis*

When using a spline for GAMs, each basis function has a coefficient

The spline is formed by weighing the basis function coefficients and summing them at each value of x

Wiggleness and Penalized fit

As in the same case with a polynomial regression of excess “wiggles” not constraining the “Wiggleness” in the way that we penalize the fit in order to prevent overfitting

W or wiggleness is defined by:

$$\int_{\mathbb{R}} [f'']^2 dx = \beta^T \mathbf{S} \beta = W$$

Constraining Wiggleness

We have to make wiggleness important by looking into the log-likelihood, or the measure of closeness to the data

The term **smoothing operator** λ defines the trade-off to find *spline* coefficients to maximize the penalized log-likelihood fit

$$\mathcal{L}_p(\beta) = \mathcal{L}(\beta) - \frac{1}{2}\lambda\beta^T\mathbf{S}\beta$$

or

$$\mathcal{L}_p = \log(\text{Likelihood}) - \lambda W$$

Selecting smooth

There are multiple methods to choose from the right amount of wiggle, some are: AIC, Mallows C_p , Maximum Likelihood(ML), and Restricted Maximum Likelihood(REML). The most commonly method is REML for it's numerical stability

There are two ways to optimize the given λ :

- Predictive: Reducing generalization error
- Bayesian: Using priors for basis coefficients

Maximizing Wiggleness

In a regular regression, the degree of freedom typically equal the predictors in the model. In the case for GAMs, we look at the smoothing *basis* of size k and consider that with **penalized** fitting, their parameters are limited. Thus, the models **effective** degrees of freedom (EDF) will not equal the size k

The models effective degrees of freedom are given by $\text{trace}(F)$ where F is the EDF matrix

$$F = (X^T W X + \sum_j \lambda_j S_j)^{-1} X^T W X$$

Generalized Additive Models in R

- Two options for packages, mgcv and gam
- mgcv is more commonly used and better supported

Smooth interactions in R

1 Bivariate

- $s(x, z, \text{bs} = \text{'tp'})$

2 Tensor products

- $\text{te}(x, z)$

Example - Simulated Data

```
library(mgcv)
set.seed(0)
sim_data <- gamSim(1, n = 400, dist="normal", scale=2)
```

Gu & Wahba 4 term additive model

```
head(sim_data)
```

R-sq.(adj) = 0.726 Deviance explained = 73.7%
GCV = 4.611 Scale est. = 4.4029 n = 400

Example - Simulated Data

```
plot(fit, pages=1, residuals=TRUE)
```

Example - Simulated Data

```
gam.check(fit)
```

Resids vs. linear pred.

Histogram of residuals

Response vs. Fitted Values

Example - mtcars

```
data("mtcars")
mtcars_gam <-
  gam(mpg ~ s(displ), data = mtcars, method = "REML")
summary(mtcars_gam)
```

Family: gaussian
Link function: identity

Formula:
mpg ~ s(displ)

Parametric coefficients:

	Estimate	Std. Error	t value	Pr(> t)
(Intercept)	20.0906	0.3788	53.04	<2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

Approximate significance of smooth terms:

	edf	Ref.df	F	p-value
s(displ)	4.884	5.904	36.3	<2e-16 ***

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

R-sq.(adj) = 0.874 Deviance explained = 89.4%
-REML = 74.101 Scale est. = 4.5918 n = 32

Example - mtcars

```
library(ggplot2)
ggplot(data = mtcars, aes(x = disp, y = mpg)) +
  theme_bw() + geom_point() +
  geom_smooth(method = "gam", formula = y ~ s(x))
```

Example - mtcars

```
gam.check(mtcars_gam)
```

Resids vs. linear pred.

Histogram of residuals

Response vs. Fitted Values

Example - mtcars

Example - Health Data - Explaining Data Set

Dataset pulled from the Department of Health & Human Services (HHS) which is a a cabinet-level department of the U.S. federal government. The Dataset provides state-aggregated data for estimated patient impact and hospital utilization by COVID-19 Patients by a State Timeseries.

<https://healthdata.gov/dataset/covid-19-estimated-patient-impact-and-hospital-capacity-state>

Example - Health Data - Data Cleaning

```
bed0cc <- read.csv("estimated_inpatient.csv", header = TRUE)
library(ggplot2)
library(tidyverse)

# Read dataset
bed0cc <- bed0cc %>%
  select(state, collection_date, Inpatient.Beds.Occupied.Estimated, Total.Inpatient.Beds) %>%
  drop_na()

# Convert from Character to Numeric and Date variable type
bed0cc$Inpatient.Beds.Occupied.Estimated <- as.factor(bed0cc$Inpatient.Beds.Occupied.Estimated)
bed0cc$Inpatient.Beds.Occupied.Estimated <- as.numeric(bed0cc$Inpatient.Beds.Occupied.Estimated)
bed0cc$Total.Inpatient.Beds <- as.factor(bed0cc$Total.Inpatient.Beds)
bed0cc$Total.Inpatient.Beds <- as.numeric(bed0cc$Total.Inpatient.Beds)
bed0cc$collection_date <- as.Date(bed0cc$collection_date)
```

Example - Health Data - Country Wide

```
# Bed Occupation for COVID-19 patients Country Wide
bedOccCW <- bedOcc %>%
  filter(state == 'CW')
ggplot(data = bedOccCW, aes(x = collection_date, y = Inpatient.Beds.Occupied.Estimated)) + geom_point() +
  geom_line(color = "black", size = 1) +
  labs(title = 'Bed Occupation by COVID patients in November in the US', x = "Date", y = "Bed Occupation by COVID patient")
```

Example - Health Data - VA

```
bedOccVA <- bedOcc %>%  
  filter(state == 'VA')  
p <- ggplot(data = bedOccVA, aes(x = collection_date, y = Inpatient.Beds.Occupied.Estimated)) + theme_bw()  
  geom_line(color = "black", size = 1) +  
  labs(title = 'Bed Occupation by COVID patients in November in Virginia', x = "Date", y = "Bed Occupation")  
p
```

Example - Health Data - LM

```
# Linear Model Fit (uses formula = y~x)
p + geom_line(color = "black", size = 1) + geom_smooth(method = 'lm', se=FALSE, color = 'blue')
```

Example - Health Data - Loess

```
# Loess Model Fit  
p + geom_line(color = "black", size = 1) + geom_smooth(method = 'loess', se=FALSE, color = 'blue')
```

Example - Health Data - GAM

```
# GAM Model Fit (formula = y ~ s(x, bs = "cs"))  
p + geom_line(color = "black", size = 1) + geom_smooth(method = 'gam', se=FALSE, color = 'red')
```

Conclusion

- The benefits of implementing GAMs provides a flexible framework to accurately model nonlinear relationships.
- It's formed from basis functions, which weigh regression functions to form larger functions known as smooths
- To control overfitting, we penalize the fit of the model by adjusting the goodness of fit
